Quantum Computers: Physical Implementations

1. Individual atoms and photons

- a. ion traps
- b. atoms in optical lattices
- c. cavity-QED

2. Superconductors

- a. Cooper-pair boxes (charge qubits)
- b. rf-SQUIDS (flux qubits)

3. Semiconductors

quantum dots

4. Other condensed-matter

- a. electrons floating on liquid helium
- b. single phosphorus atoms in silicon

Conflicting requirements

Qubits must interact strongly with one another (on demand)...

Quantum Computations with Cold Trapped Ions

J. I. Cirac and P. Zoller*

---- Requirements ---- (David DiVincenzo, IBM)

- 1) Scalable system of qubits
- 2) Initialization (i.e. to $|000\dots\rangle$)
- 3) Decoherence times \gg gate operation time
- 4) A "universal" set of quantum gates
- 5) A qubit-specific measurement capability

Two big challenges to tackle:

- **Robustness.** We need long qubit coherence times and high fidelity operations to reach error correction thresholds for stable quantum computing ($<10^{-4}$ error rate).
- **Scalability.** At the same time we need a scalable design to reach a useful number of qubits.

Quantum Computations with Cold Trapped Ions

J. I. Cirac and P. Zoller*

*Institut für Theoretische Physik, Universität Innsbruck, Technikerstrasse 25, A-6020 Innsbruck, Austria
(Received 30 November 1994)*

A quantum computer can be implemented with cold ions confined in a linear trap and interacting with laser beams. Quantum gates involving any pair, triplet, or subset of ions can be realized by coupling the ions through the collective quantized motion. In this system decoherence is negligible, and the measurement (readout of the quantum register) can be carried out with a high efficiency.
