Design Entry

- Schematic entry/editing used to be the standard method in industry and universities.
- Used in EECS150 until 2002
  - Schematics are intuitive. They match our use of gate-level or block diagrams.
  - Somewhat physical. They imply a physical implementation.
  - Require a special tool (editor).
  - Unless hierarchy is carefully designed, schematics can be confusing and difficult to follow on large designs.

- Hardware Description Languages (HDLs) are the new standard
  - except for PC board design, where schematics are still used.

Hardware Description Languages

- **Basic Idea:**
  - Language constructs describe circuits with two basic forms:
    - **Structural descriptions:** connections of components. Nearly one-to-one correspondence to schematic diagram.
    - **Behavioral descriptions:** use high-level constructs (similar to conventional programming) to describe the circuit function.
  - Originally invented for simulation.
    - Now "logic synthesis" tools exist to automatically convert from HDL source to circuits.
    - High-level constructs greatly improves designer productivity.
    - However, this may lead you to falsely believe that hardware design can be reduced to writing programs!

  - **"Structural" example:**
    ```verilog
    Decoder(output x0,x1,x2,x3;
             inputs a,b)
    {
      wire abar, bbar;
      inv(bbar, b);
      inv(abar, a);
      and(x0, abar, bbar);
      and(x1, abar, b   );
      and(x2, a,    bbar);
      and(x3, a,    b   );
    }
    ```

  - **"Behavioral" example:**
    ```verilog
    Decoder(output x0,x1,x2,x3;
             inputs a,b)
    {
      case [a b]
          00: [x0 x1 x2 x3] = 0x1;
          01: [x0 x1 x2 x3] = 0x2;
          10: [x0 x1 x2 x3] = 0x4;
          11: [x0 x1 x2 x3] = 0x8;
      endcase;
    }
    ```

*Warning: this is a fake HDL!*

*Describing hardware with a language is similar, however, to writing a parallel program.*
Sample Design Methodology

Hierarchically defines structure and/or function of circuit.

HDL Specification

Simulation
Verification: Does the design behave as required with regards to function, timing, and power consumption?

Synthesis
Maps specification to resources of implementation platform (FPGA or custom silicon).

Note: This in not the entire story. Other tools are useful for analyzing HDL specifications. More on this later.

Verilog

- A brief history:
  - Invented as simulation language. Synthesis was an afterthought. Many of the basic techniques for synthesis were developed at Berkeley in the 80’s and applied commercially in the 90’s.
  - Around the same time as the origin of Verilog, the US Department of Defense developed VHDL (A double acronym! VHSIC (Very High-Speed Integrated Circuit) HDL). Because it was in the public domain it began to grow in popularity.
  - Afraid of losing market share, Cadence opened Verilog to the public in 1990.
  - Verilog is the language of choice of Silicon Valley companies, initially because of high-quality tool support and its similarity to C-language syntax.
  - VHDL is still popular within the government, in Europe and Japan, and some Universities.
  - Most major CAD frameworks now support both.
  - Latest Verilog version is “system Verilog”.
  - Latest HDL: C++ based. OSCI (Open System C Initiative).
Verilog Introduction

• A **module** definition describes a component in a circuit

• Two ways to describe module contents:
  – Structural Verilog
    • List of sub-components and how they are connected
    • Just like schematics, but using text
    • Tedious to write, hard to decode
    • You get precise control over circuit details
    • May be necessary to map to special resources of the FPGA
  – Behavioral Verilog
    • Describe what a component does, not how it does it
    • Synthesized into a circuit that has this behavior
    • Result is only as good as the tools

• Build up a hierarchy of modules. Top-level module is your entire design (or the environment to test your design).

TOP DOWN ARCH (1)

• Top Down Refinement Process
• Start Here:
TOP DOWN ARCH (2)

- End Here:

```
If(a == 1)
   Z = A + B;
Else
   Z = A + C;
```

```
if(a == 1)
   aux = B;
else
   aux = C;
Z = A + aux;
```

“Think Hardware (1)”
“Think Hardware (2)”

assign B = 3;
assign Z = A * B;

assign Z = A + 2 * A;

“Think Hardware (3)”

assign aux = {1'b0, A[n-1:1]} + A[n-1:0];
assign Z = {aux, A[0]};
Verilog Modules and Instantiation

- Modules define circuit components.
- Instantiation defines hierarchy of the design.

```verilog
module addr_cell (a, b, cin, s, cout);
    input  a, b, cin;
    output s, cout;
endmodule

module adder (A, B, S);
    addr_cell ac1 (              );
endmodule
```

Note: A module is not a function in the C sense. There is no call and return mechanism. Think of it more like a hierarchical data structure.

Structural Model - XOR example

```verilog
module xor_gate (out, a, b);
    input  a, b;
    output out;
    wire   aBar, bBar, t1, t2;
    not invA (aBar, a);
    not invB (bBar, b);
    and and1 (t1, a, bBar);
    and and2 (t2, b, aBar);
    or  or1 (out, t1, t2);
endmodule
```

Notes:
- The instantiated gates are not "executed". They are active always.
- xor gate already exists as a built-in (so really no need to define it).
- Undeclared variables assumed to be wires. Don’t let this happen to you!
Structural Example: 2-to1 mux

/* 2-input multiplexor in gates */
module mux2 (in0, in1, select, out);
  input in0, in1, select;
  output out;
  wire s0, w0, w1;
  not (s0, select);
  and (w0, s0, in0),
       (w1, select, in1);
  or  (out, w0, w1);
endmodule // mux2

Built-ins don't need instance names

Multiple instances can share the same "master" name.

Built-ins gates can have > 2 inputs. Ex:
and (w0, a, b, c, d);

Institution, Signal Array, Named ports

module mux4 (in0, in1, in2, in3, select, out);
  input in0, in1, in2, in3;
  input [1:0] select;
  output out;
  wire w0, w1, w2;
  mux2 m0 (.select(select[0]), .in0(in0), .in1(in1), .out(w0)),
          m1 (.select(select[0]), .in0(in2), .in1(in3), .out(w1)),
          m3 (.select(select[1]), .in0(w0), .in1(w1), .out(out));
endmodule // mux4

Signal array. Declares select[1], select[0]

Named ports. Highly recommended.
Simple Behavioral Model

module foo (out, in1, in2);
    input         in1, in2;
    output        out;

    assign out = in1 & in2;

endmodule

Shorthand for explicit instantiation of "and" gate (in this case).

The assignment continuously happens, therefore any change on the rhs is reflected in out immediately (except for the small delay associated with the implementation of the &).

Not like an assignment in C that takes place when the program counter gets to that place in the program.

Example - Ripple Adder

module FullAdder(a, b, ci, r, co);
    input a, b, ci;
    output r, co;

    assign r = a ^ b ^ ci;
    assign co = a&ci | a&b | b&cin;

endmodule

module Adder(A, B, R);
    input [3:0] A;
    input [3:0] B;
    output [4:0] R;

    wire c1, c2, c3;
    FullAdder
    add0(.a(A[0]), .b(B[0]), .ci(1'b0), .co(c1), .r(R[0]) )
    add1(.a(A[1]), .b(B[1]), .ci(c1), .co(c2), .r(R[1]) )
    add2(.a(A[2]), .b(B[2]), .ci(c2), .co(c3), .r(R[2]) )
    add3(.a(A[3]), .b(B[3]), .ci(c3), .co(R[4]), .r(R[3]) )

endmodule
Behavioral vs Structural (1)

- Rule of thumb:
  - Behavioral doesn’t have sub-components
  - Structural has sub-components:
    - Instantiated Modules
    - Instantiated Gates
    - Instantiated Primitives
- Most levels are mixed

Behavioral vs Structural (2)
Behavioral Example

- Behavioral Only
- No Instantiations

Behavioral and Structural

- Behavioral:
  - Adder
  - Register
- Structural:
  - Top
  - Two Instantiations
low level details

Continuous Assignment Examples

```verilog
assign R = X | (Y & ~Z);
assign r = &X;
assign R = (a == 1'b0) ? X : Y;
assign P = 8'hff;
assign P = X * Y;
assign P[7:0] = {4{X[3]}, X[3:0]};
assign {cout, R} = X + Y + cin;
assign Y = A << 2;
assign Y = {A[1], A[0], 1'b0, 1'b0};

### Conditional Operator

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>

</thead>
<tbody>
<tr>

<td>conditional</td>
</tr>
</tbody>
</table>

### Constants:

- **14** ordinary decimal number
- **-14** 2’s complement representation
- **12'b0000_0100_0110** binary number (“’” is ignored)
- **12'h046** hexadecimal number with 12 bits

### Verilog Numbers

- If A = 0110 (6) and B = 1010(-6)
  - C = 10000 not 00000
  - i.e., B is zero-padded, not sign-extended

### Signal Values:

By default, Values are unsigned

- if A = 0110 (6) and B = 1010(-6)
  - C = 10000 not 00000
  - i.e., B is zero-padded, not sign-extended

### wire signed [31:0] x;

Declares a signed (2’s complement) signal array.
Non-continuous Assignments
A bit strange from a hardware specification point of view.
Shows off Verilog roots as a simulation language.

“always” block example:

module and_or_gate (out, in1, in2, in3);
  input  in1, in2, in3;
  output out;
  reg   out;

  always @(in1 or in2 or in3) begin
    out = (in1 & in2) | in3;
  end
endmodule

Isn’t this just: assign out = (in1 & in2) | in3;? Why bother?

Always Blocks
Always blocks give us some constructs that are impossible or awkward in continuous assignments.

case statement example:

module mux4 (in0, in1, in2, in3, select, out);
  input in0,in1,in2,in3;
  input [1:0] select;
  output      out;
  reg         out;

  always @ (in0 in1 in2 in3 select)
    case (select)
      2'b00: out=in0;
      2'b01: out=in1;
      2'b10: out=in2;
      2'b11: out=in3;
    endcase
endmodule // mux4

Could we just do this with nested “if”s? Well yes and no!
Always Blocks

Nested if-else example:

```verilog
module mux4 (in0, in1, in2, in3, select, out);
    input in0, in1, in2, in3;
    input [1:0] select;
    output      out;
    reg         out;

    always @ (in0 in1 in2 in3 select)
        if (select == 2'b00) out=in0;
        else if (select == 2'b01) out=in1;
        else if (select == 2'b10) out=in2;
        else out=in3;
endmodule // mux4
```

Nested if structure leads to "priority logic" structure, with different delays for different inputs (in3 to out delay > than in0 to out delay). Case version treats all inputs the same.

Review - Ripple Adder Example

```verilog
module FullAdder(a, b, ci, r, co);
    input a, b, ci;
    output r, co;

    assign r = a ^ b ^ ci;
    assign co = a&ci + a&b + b&cin;
endmodule

module Adder(A, B, R);
    input [3:0] A;
    input [3:0] B;
    output [4:0] R;

    wire c1, c2, c3;
    FullAdder
    add0 (.a(A[0]), .b(B[0]), .ci(1'b0), .co(c1), .r(R[0])) ,
    add1 (.a(A[1]), .b(B[1]), .ci(c1), .co(c2), .r(R[1])) ,
    add2 (.a(A[2]), .b(B[2]), .ci(c2), .co(c3), .r(R[2])) ,
    add3 (.a(A[3]), .b(B[3]), .ci(c3), .co(R[4]), .r(R[3])) ;
endmodule
```
Example - Ripple Adder Generator

Parameters give us a way to generalize our designs. A module becomes a "generator" for different variations. Enables design/module reuse. Can simplify testing.

```
module Adder(A, B, R);
parameter N = 4;
input [N-1:0] A;
input [N-1:0] B;
output [N:0] R;
wire [N:0] C;
generate
for (i=0; i<N; i=i+1)
begin:bit
    FullAdder add(.a(A[i], .b(B[i]), .ci(C[i]), .co(C[i+1]), .r(R[i]));
end
endgenerate
assign C[0] = 1'b0;
assign R[N] = C[N];
endmodule
```

More on Generate Loop

Permits variable declarations, modules, user defined primitives, gate primitives, continuous assignments, initial blocks and always blocks to be instantiated multiple times using a for-loop.

```
// Gray-code to binary-code converter
module gray2bin1 (bin, gray);
parameter SIZE = 8;
output [SIZE-1:0] bin;
input [SIZE-1:0] gray;

generate
for (i=0; i<SIZE; i=i+1) begin:
    assign bin[i] = ^gray[SIZE-1:i];
end
endgenerate
endmodule
```

variable exists only in the specification - not in the final circuit.

Keywords that denotes synthesis-time operations

For-loop creates instances

Generate if-else-if based on an expression that is deterministic at the time the design is synthesized.

Generate case : selecting case expression must be deterministic at the time the design is synthesized.
Verilog in EECS150

- We will primarily use behavioral modeling along with instantiation to 1) build hierarchy and, 2) map to FPGA resources not supported by synthesis.
- Favor continuous assign and avoid always blocks unless:
  - no other alternative: ex: state elements, case
  - helps readability and clarity of code: ex: large nested if else
- Use named ports.
- Verilog is a big language. This is only an introduction.
  - Our text book is a good source. Read and use chapter 4.
  - Be careful of what you read on the web. Many bad examples out there.
  - We will be introducing more useful constructs throughout the semester. Stay tuned!

Final thoughts on Verilog Examples

Verilog looks like C, but it describes hardware
Multiple physical elements with parallel activities and temporal relationships.

A large part of digital design is knowing how to write Verilog that gets you the desired circuit. First understand the circuit you want then figure out how to code it in Verilog. If you do one of these activities without the other, you will struggle. These two activities will merge at some point for you.

Be suspicious of the synthesis tools! Check the output of the tools to make sure you get what you want.
Putting it all together ... a SLICEL.

The previous slides explain all SLICEL features.

About 50% of the 17,280 slices in an LX110T are SLICELs.

The other slices are SLICEMs, and have extra features.
