TA Name:	
Discussion Section Time:	

General Information:

This is a **closed book and notes** examination. You have 90 minutes to answer as many questions as possible. The number in parentheses at the beginning of each question indicates the number of points given to the question; there are 100 points in all. You should read **all** of the questions before starting the exam, as some of the questions are substantially more time consuming.

Write all of your answers directly on this paper. *Make your answers as concise as possible.* If there is something in a question that you believe is open to interpretation, then please ask us about it!

Good Luck!!

Problem	Possible	Score
1	19	
2	36	
3	23	
4	22	
Total	100	

d. (7 points) Read-ahead.

i) (3 points) Give a brief (2-3 sentences) description of read-ahead.

ii) (2 points) Briefly (2-3 sentences) state why read-ahead is useful.

iii) (2 points) Briefly (2-3 sentences) state what happens if you read ahead too much.

e. (7 points) RAID

i) (3 points) Give a brief (2-3 sentences) description of RAID 5.

ii) (2 points) How many disk failures can RAID 5 tolerate without losing data?

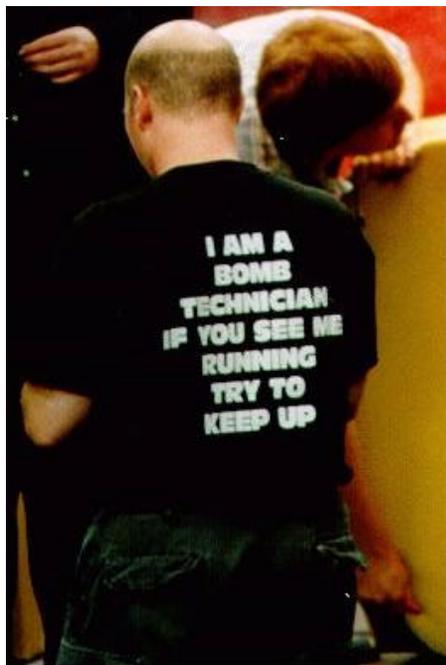

iii) (2 points) How would you reconstruct a failed disk?

No Credit – **Problem X** (000000000000 points)

The importance of synchronization... or You're first – after me (This Only Happens in New York City).

Race Condition

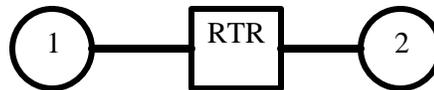

3. (23 points total) Reliable Peer-to-Peer (P2P) File Sharing.

Two computers running a P2P application using TCP/IP for connections are connected via a router (see below). To write data packets to the network, the P2P application issues a system call, and the OS copies the data first to a kernel buffer and then uses DMA to copy the data to the network controller board. Immediately after receiving the data, the controller generates one or more packets and sends them.

The packets travel one hop to router RTR, which will in turn forward the packets to their final destination. *Assume that no packets will be lost, and assume that the processing time at the router is negligible, and a router must wait for the entire packet to arrive before forwarding it.*

The receiving network controller uses DMA to copy the data it receives to memory, and when the last bit arrives and is transferred, it interrupts the CPU. The OS copies the data to the P2P application's buffer in user space. After the copy completes, the OS sends back a one-byte acknowledgement to the sending OS. *For simplicity, you may treat acknowledgements as if they are zero bytes long. Assume that a sender uses a send window-based acknowledgement protocol.*

System Parameters:

- Time to process an interrupt, $T_{\text{int}} = 1.5$ millisecond
 - CPU cycle time, $T_{\text{CPU}} = 10$ nanoseconds
 - Packet size, $N_{\text{pkt}} = 1,000$ bytes (ignore headers)
 - Time to copy or DMA one byte, $T_{\text{copy}} = 1$ microsecond
 - Latency of a link, $T_{\text{link}} = 3$ milliseconds
 - Bandwidth of links, $B = 8,000,000$ bit/sec
 - Send window $N_{\text{win}} = 1$ packet
 - Retransmission timeout, $T_{\text{retran}} = 400$ milliseconds
- a. (7 points) Compute T_{pkt} , the time to reliably send a single packet from a P2P application on computer 2 to a P2P application on computer 1 over a link with no losses.

- b. (3 points) What is the maximum or peak rate at which one process can reliably send data to another process?
- c. (4 points) In terms of T_{pkt} , how long does it take to reliably send an .mp3 file from computer 2 to computer 1 if the file is 4,000,000 bytes in size (assuming the links have no losses)?
- d. (5 points) If we use a send window of 40 outstanding packets instead, what is the maximum rate at which one process can reliably send data to another process (assuming the links have no losses)?
- e. (4 points) If we use a send window of 40 outstanding packets instead, how long does it take to reliably send an .mp3 file from computer 2 to computer 1 if the file is 4,000,000 bytes in size (assuming the links have no losses)?
