

Section Handout #6: Probability

In Class

Question 1. Consider the following 3-sided dice with the given side values. Assume the dice are all fair (each side has probability $\frac{1}{3}$) and all rolls are independent.

- A: 2, 2, 5
- B: 1, 4, 4
- C: 3, 3, 3

- a. What is the expected value of each die?
- b. Consider the indicator function $\text{better}(X,Y)$ which has value 1 if $X>Y$ and value -1 if $X<Y$. What are the expected values of $\text{better}(A, B)$, $\text{better}(B, C)$, $\text{better}(C, A)$? Why are these sometimes called non-transitive dice?

Question 2. On a day when an assignment is due ($A=a$), the newsgroup tends to be busy ($B=b$), and the computer lab tends to be full ($C=c$). Consider the following conditional probability tables for the domain, where $A = \{a, \neg a\}$, $B = \{b, \neg b\}$, $C = \{c, \neg c\}$.

P(A)	P(B A)	P(C A)																																				
<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="width: 50%;">A</th> <th style="width: 50%;">P</th> </tr> </thead> <tbody> <tr> <td>a</td> <td>0.20</td> </tr> <tr> <td>$\neg a$</td> <td>0.80</td> </tr> </tbody> </table>	A	P	a	0.20	$\neg a$	0.80	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="width: 33%;">B</th> <th style="width: 33%;">A</th> <th style="width: 33%;">P</th> </tr> </thead> <tbody> <tr> <td>b</td> <td>a</td> <td>0.90</td> </tr> <tr> <td>$\neg b$</td> <td>a</td> <td>0.10</td> </tr> <tr> <td>b</td> <td>$\neg a$</td> <td>0.40</td> </tr> <tr> <td>$\neg b$</td> <td>$\neg a$</td> <td>0.60</td> </tr> </tbody> </table>	B	A	P	b	a	0.90	$\neg b$	a	0.10	b	$\neg a$	0.40	$\neg b$	$\neg a$	0.60	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="width: 33%;">C</th> <th style="width: 33%;">A</th> <th style="width: 33%;">P</th> </tr> </thead> <tbody> <tr> <td>c</td> <td>a</td> <td>0.70</td> </tr> <tr> <td>$\neg c$</td> <td>a</td> <td>0.30</td> </tr> <tr> <td>c</td> <td>$\neg a$</td> <td>0.50</td> </tr> <tr> <td>$\neg c$</td> <td>$\neg a$</td> <td>0.50</td> </tr> </tbody> </table>	C	A	P	c	a	0.70	$\neg c$	a	0.30	c	$\neg a$	0.50	$\neg c$	$\neg a$	0.50
A	P																																					
a	0.20																																					
$\neg a$	0.80																																					
B	A	P																																				
b	a	0.90																																				
$\neg b$	a	0.10																																				
b	$\neg a$	0.40																																				
$\neg b$	$\neg a$	0.60																																				
C	A	P																																				
c	a	0.70																																				
$\neg c$	a	0.30																																				
c	$\neg a$	0.50																																				
$\neg c$	$\neg a$	0.50																																				

- a. Construct the joint distribution out of these conditional probabilities tables assuming B and C are independent given A.
- b. What is the marginal distribution $P(B,C)$? Are these two variables absolutely independent in this model? Justify your answer using the actual probabilities, not your intuitions.
- c. What is the posterior distribution over A given that $B=b$, $P(A | B=b)$? What is the posterior distribution over A given that $C=c$, $P(A | C=c)$? What about $P(A | B=b, C=c)$? Explain the pattern among these posteriors and why it holds.

Homework

Question 1. Assume that a joint distribution over two variables, $X = \{x, \neg x\}$ and $Y = \{y, \neg y\}$ is known to have the marginal distributions $P(x) = P(\neg x) = P(y) = P(\neg y)$. Give joint distributions satisfying these marginals for each of these conditions:

- a. X and Y are independent

- b. Observing $Y=y$ increases the belief in $X=x$, i.e. $P(x | y) > P(x)$
- c. Observing $Y=y$ decreases the belief in $X=x$, i.e. $P(x | y) < P(x)$

Question 2. Sometimes, there is traffic (cars) on the freeway ($C=c$). This could either be because of a ball game ($B=b$) or because of an accident ($A=a$). Consider the following joint probability table for the domain, where $A = \{a, \neg a\}$, $B = \{b, \neg b\}$, $C = \{c, \neg c\}$.

$P(A, B, C)$

A	B	C	P
a	b	c	0.018
a	b	$\neg c$	0.002
a	$\neg b$	c	0.126
a	$\neg b$	$\neg c$	0.054
$\neg a$	b	c	0.064
$\neg a$	b	$\neg c$	0.016
$\neg a$	$\neg b$	c	0.072
$\neg a$	$\neg b$	$\neg c$	0.648

- a. What is the distribution $P(A,B)$? Are A and B independent in this model given no evidence? Justify your answer using the actual probabilities, not your intuitions.
- b. What is the marginal distribution over A given no evidence?
- c. How does this change if we observe that $C=c$; what is the posterior distribution $P(A | C=c)$? Does this change intuitively make sense? Why or why not?
- d. What is the conditional distribution over A if we then learn there is a ball game, $P(A | B=b, C=c)$? Does it make sense that observing B should cause this update to A (called explaining-away)? Why or why not?
