

## Announcements

---

- Homework 5 is due Tuesday 10/15 @ 11:59pm
- Project 3 is due Thursday 10/24 @ 11:59pm
- Midterm 2 is on Monday 10/28 7pm-9pm

## 61A Lecture 16

---

Friday, October 11

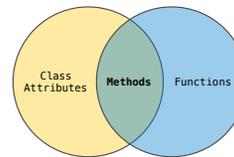

## Attributes

## Terminology: Attributes, Functions, and Methods

---

All objects have attributes, which are name-value pairs  
Classes are objects too, so they have attributes  
Instance attribute: attribute of an instance  
Class attribute: attribute of the class of an instance

**Terminology:**

**Python object system:**

*Functions* are objects.

*Bound methods* are also objects: a function that has its first parameter "self" already bound to an instance.

*Dot expressions* evaluate to bound methods for class attributes that are functions.

`<instance>.<method_name>`

---

## Looking Up Attributes of an Object

---

`<expression> . <name>`

To evaluate a dot expression:

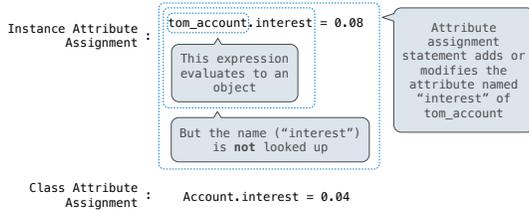

1. Evaluate the `<expression>`.
  2. `<name>` is matched against the instance attributes.
  3. If not found, `<name>` is looked up in the class.
  4. That class attribute value is returned **unless it is a function**, in which case a *bound method* is returned.
- 

## Attribute Assignment

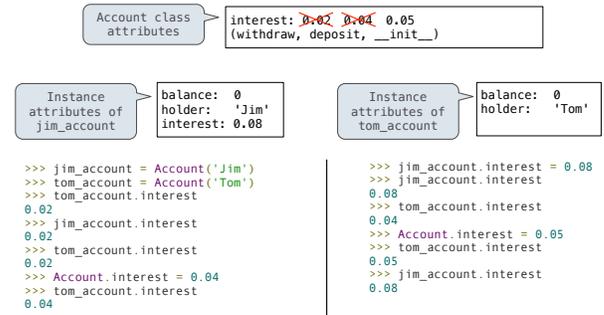

## Assignment to Attributes

Assignment statements with a dot expression on their left-hand side affect attributes for the object of that dot expression

- If the object is an instance, then assignment sets an instance attribute
- If the object is a class, then assignment sets a class attribute

## Attribute Assignment Statements

## Inheritance

### Inheritance

Inheritance is a method for relating classes together.

A common use: Two similar classes differ in their degree of specialization.

The specialized class may have the same attributes as the general class, along with some special-case behavior.

```
class <name>(<base class>):
    <suite>
```

Conceptually, the new subclass "shares" attributes with its base class.

The subclass may *override* certain inherited attributes.

Using inheritance, we implement a subclass by specifying its differences from the base class.

## Inheritance Example

A CheckingAccount is a specialized type of Account.

```
>>> ch = CheckingAccount('Tom')
>>> ch.interest # Lower interest rate for checking accounts
0.01
>>> ch.deposit(20) # Deposits are the same
20
>>> ch.withdraw(5) # Withdrawals incur a $1 fee
14
```

Most behavior is shared with the base class Account

```
class CheckingAccount(Account):
    """A bank account that charges for withdrawals."""
    withdraw_fee = 1
    interest = 0.01
    def withdraw(self, amount):
        return Account.withdraw(self, amount + self.withdraw_fee)
```

## Looking Up Attribute Names on Classes

Base class attributes *aren't copied* into subclasses!

To look up a name in a class.

1. If it names an attribute in the class, return the attribute value.
2. Otherwise, look up the name in the base class, if there is one.

```
>>> ch = CheckingAccount('Tom') # Calls Account.__init__
>>> ch.interest # Found in CheckingAccount
0.01
>>> ch.deposit(20) # Found in Account
20
>>> ch.withdraw(5) # Found in CheckingAccount
14
```

(Demo)

## Object-Oriented Design

### Designing for Inheritance

Don't repeat yourself; use existing implementations.

Attributes that have been overridden are still accessible via class objects.

Look up attributes on instances whenever possible.

```
class CheckingAccount(Account):
    """A bank account that charges for withdrawals."""
    withdraw_fee = 1
    interest = 0.01
    def withdraw(self, amount):
        return Account.withdraw(self, amount + self.withdraw_fee)
```

Attribute look-up  
on base class

Preferred to CheckingAccount.withdraw\_fee  
to allow for specialized accounts

### Inheritance and Composition

Object-oriented programming shines when we adopt the metaphor.

Inheritance is best for representing *is-a* relationships.

E.g., a checking account **is a** specific type of account.

So, CheckingAccount inherits from Account.

Composition is best for representing *has-a* relationships.

E.g., a bank **has a** collection of bank accounts it manages.

So, A bank has a list of accounts as an attribute.

(Demo)

### Multiple Inheritance

### Multiple Inheritance

```
class SavingsAccount(Account):
    deposit_fee = 2
    def deposit(self, amount):
        return Account.deposit(self, amount - self.deposit_fee)
```

A class may inherit from multiple base classes in Python.

CleverBank marketing executive wants:

- Low interest rate of 1%
- A \$1 fee for withdrawals
- A \$2 fee for deposits
- A free dollar when you open your account

```
class AsSeenOnTVAccount(CheckingAccount, SavingsAccount):
    def __init__(self, account_holder):
        self.holder = account_holder
        self.balance = 1 # A free dollar!
```

### Multiple Inheritance

A class may inherit from multiple base classes in Python.

```
class AsSeenOnTVAccount(CheckingAccount, SavingsAccount):
    def __init__(self, account_holder):
        self.holder = account_holder
        self.balance = 1 # A free dollar!
```

Instance attribute

```
>>> such_a_deal = AsSeenOnTVAccount("John")
>>> such_a_deal.balance
1
```

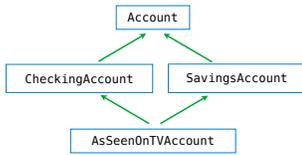

SavingsAccount method

```
>>> such_a_deal.deposit(20)
19
```

CheckingAccount method

```
>>> such_a_deal.withdraw(5)
13
```

## Resolving Ambiguous Class Attribute Names

```
>>> such_a_deal = AsSeenOnTVAccount("John")
>>> such_a_deal.balance
1
>>> such_a_deal.deposit(20)
19
>>> such_a_deal.withdraw(5)
13
```

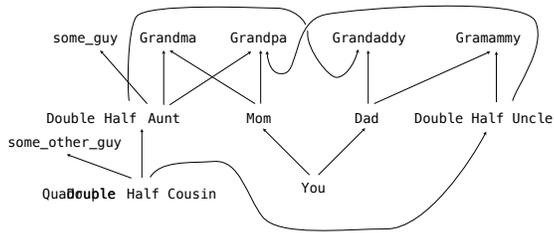

Instance attribute

SavingsAccount method

CheckingAccount method

## Complicated Inheritance

## Biological Inheritance

Moral of the story: Inheritance can be complicated, so don't overuse it!
