

## Lecture #2: Functions, Expressions, Environments

- From last lecture: *Values* are data we want to manipulate and in particular,
- *Functions* are values that perform computations on values.
- *Expressions* denote computations that produce values.
- Today, we'll look at them in some detail at how functions operate on data values and how expressions denote these operations.
- As usual, although our concrete examples all involve Python, the actual concepts apply almost universally to programming languages.

## Functions

- We're going to use this notation to denote functions:

`abs(number):`      `add(left, right)`

- The green parenthesized lists indicate the number of *parameter values* or *inputs* the functions operate on (this information is also known as a function's *signature*).
- For our purposes, the blue name is simply a helpful comment to suggest what the function does, and the specific (green) parameter names are likewise just helpful hints.
- (Python actually maintains this *intrinsic name* and the parameter names internally, but this is not a universal feature of programming languages).

CS61A: Lecture #2 2

## Pure Functions

- The fundamental operation on function values is to *call* or *invoke* them, which means giving them one value for each formal parameter and having them produce the result of their computation on these values:

`-5 > abs(number):`      `> 5`

`(29, 13) > add(left, right)`      `> 42`

- These two functions are *pure*: their output depends only on their input parameters' values, and they do nothing in response to a call but compute a value.

CS61A: Lecture #2 3

## Impure Functions

- Functions may do additional things when called besides returning a value.
- We call such things *side effects*.
- Example: the built-in `print` function:

`-5 > print(• • •)`      `> None`

↓  
*display text '-5'*

- Displaying text is `print`'s side effect. It's value, in fact, is generally useless (always the null value).

## Call Expressions

- A call expression denotes the operation of calling a function.
- Consider `add(2, 3)`:

`add` ( `2` , `3` )  
Operator    Operand 0    Operand 1

- The operator and the operands are all themselves expressions (recursion again).
- To evaluate this call expression:
  - Evaluate the operator (let's call the value  $C$ );
  - Evaluate the operands in the order they appear (let's call the values  $P_0$  and  $P_1$ );
  - Call  $C$  (which must be a function) with parameters  $P_0$  and  $P_1$ .
- Together with the definitions for base cases (mostly literal expressions and symbolic names), this describes how to evaluate any call.

## Example: From Expression to Value

Let's evaluate the expression `mul(add(2, mul(0x4, 0x6)), add(0x3, 005))`. In the following sequence, values are shown in `boxes`. Everything outside a box is an expression.

- `mul(add(2, mul(0x4, 0x6)), add(0x3, 005))`
- `mul(left, right)` ( `add(2, mul(0x4, 0x6))` , `add(0x3, 005)` )
- `mul(left, right)` ( `add(left, right)` ( `2` , `mul(left, right)` ( `4` , `6` ) ) , `add(0x3, 005)` )
- `mul(left, right)` ( `add(left, right)` ( `2` , `24` ) , `add(0x3, 005)` )
- `mul(left, right)` ( `26` , `add(0x3, 005)` )
- `mul(left, right)` ( `26` , `add(left, right)` ( `3` , `5` ) )
- `mul(left, right)` ( `26` , `8` )
- `208`.

## Example: Print

What about an expression with side effects?

- `print(print(1), print(2))`
- `print(•••)` (`print(•••)`) (`1`), `print(2)`
- `print(•••)` (`None`, `print(2)`)  
and print '1'.
- `print(•••)` (`None`, `print(•••)`) (`2`)
- `print(•••)` (`None`, `None`)  
and print '2'.
- `None`  
and print 'None None'.

## Names

- Evaluating expressions that are literals is easy: the literal's text gives all the information needed.
- But how did I evaluate names like `add`, `mul`, or `print`?
- Deduction: there must be another source of information.
- We'll use the concept of an *environment* to explain this.

CS61A: Lecture #2 8

## Environments

- An *environment* is a mapping from names to values.
- We say that a name is *bound to* a value in this environment.
- In its simplest form, it consists of a single *global environment frame*:

CS61A: Lecture #2 9

## Environments and Evaluation

- Every expression is evaluated in an environment, which supplies the meanings of any names in it.
- Evaluating an expression typically involves first evaluating its subexpressions (the operators and operands of calls, the operands of conventional expressions such as  $x*(y+z)$ , ...).
- These subexpressions are evaluated in the same environment as the expression that contains them.
- Once their subexpressions (operator + operands) are evaluated, calls to user-defined functions must evaluate the expressions and statements from the definition of those functions.

CS61A: Lecture #2 10

## Evaluating User-Defined Function Calls

- Consider the expression `square(mul(x, x))` after executing

```
from operator import mul
def square(x):
    return mul(x, x)
x = -2
```

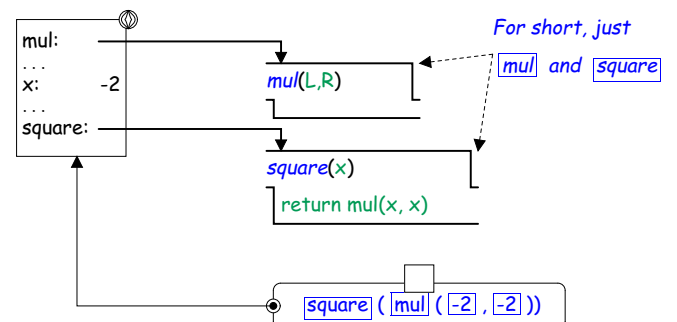

Last modified: Thu Mar 29 15:06:17 2012

CS61A: Lecture #2 11

## Evaluating User-Defined Function Calls (II)

- First evaluate the subexpressions of `square(mul(x, x))` in the global environment:

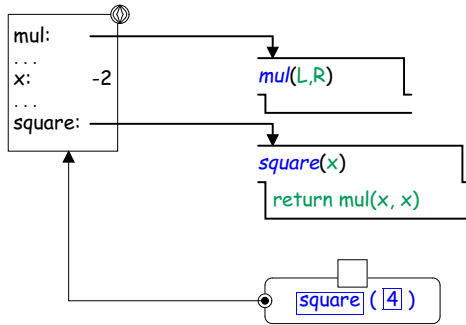

- Evaluating subexpressions `x`, `mul`, and `square` takes values from the expression's environment.

CS61A: Lecture #2 12

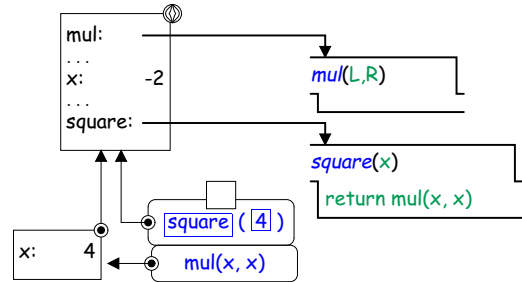

### Evaluating User-Defined Functions Calls (III)

- Then perform the primitive multiply function:

### Evaluating User-Defined Functions Calls (IV)

- To explain parameter to user-defined `square` function, extend environment with a *local environment frame*, attached to the frame in which `square` was defined (the global one in this case), and giving `x` the operand value.
- Now replace original call with evaluating body of `square` in the new local environment.

### Evaluating User-Defined Functions Calls (V)

- When we evaluate `mul(x, x)` in this new environment, we get the same value as before for `mul`, but the local value for `x`.
