### CS61B Lecture #24

Today:

- Sorting algorithms: why?
- Insertion sort

#### **Readings for Today:** DS(IJ), Chapter 8;

# Purposes of Sorting

- Sorting supports searching
- Binary search standard example
- Also supports other kinds of search:
  - Are there two equal items in this set?
  - Are there two items in this set that both have the same value for property X?
  - What are my nearest neighbors?
- Used in numerous unexpected algorithms, such as convex hull (smallest convex polygon enclosing set of points).

### Some Definitions

- A sort is a *permutation* (re-arrangement) of a sequence of elements that brings them into order, according to some *total order*. A total order,  $\leq$ , is:
  - Total:  $x \leq y$  or  $y \leq x$  for all x, y.
  - Reflexive:  $x \preceq x$ ;
  - Antisymmetric:  $x \leq y$  and  $y \leq x$  iff x = y.
  - Transitive:  $x \leq y$  and  $y \leq z$  implies  $x \leq z$ .
- However, our orderings may allow unequal items to be equivalent:
  - E.g., can be two dictionary definitions for the same word: if entries sorted only by word, then sorting could put either entry first.
  - A sort that does not change the relative order of equivalent entries is called *stable*.

# Classifications

- Internal sorts keep all data in primary memory
- External sorts process large amounts of data in batches, keeping what won't fit in secondary storage (in the old days, tapes).
- Comparison-based sorting assumes only thing we know about keys is order
- Radix sorting uses more information about key structure.
- Insertion sorting works by repeatedly inserting items at their appropriate positions in the sorted sequence being constructed.
- Selection sorting works by repeatedly selecting the next larger (smaller) item in order and adding it one end of the sorted sequence being constructed.

### Sorting by Insertion

- Simple idea:
  - starting with empty sequence of outputs.
  - add each item from input, *inserting* into output sequence at right point.
- Very simple, good for small sets of data.
- With vector or linked list, time for find + insert of one item is at worst  $\Theta(k)$ , where k is # of outputs so far.
- $\bullet$  So gives us  ${\cal O}(N^2)$  algorithm. Can we say more?

#### Inversions

- $\bullet$  Can run in  $\Theta(N)$  comparisons if already sorted.
- Consider a typical implementation for arrays:

```
for (int i = 1; i < A.length; i += 1) {
    int j;
    Object x = A[i];
    for (j = i-1; j >= 0; j -= 1) {
        if (A[j].compareTo (x) <= 0) /* (1) */
            break;
        A[j+1] = A[j];
    }
    A[j+1] = x;
}</pre>
```

- ullet #times (1) executes pprox how far  ${f x}$  must move.
- $\bullet$  If all items within K of proper places, then takes O(KN) operations.
- Thus good for any amount of *nearly sorted* data.
- One measure of unsortedness: # of inversions: pairs that are out of order (= 0 when sorted, N(N-1)/2 when reversed).
- Each step of j decreases inversions by 1.
