1 Javaian Rhapsody

Next to each line, write out what you think the code will do when it is run. Assume the Singer class exists and that the code below compiles.

```java
String disagree = "no";
int x = 7;
Singer queen = new Singer("Queen");

while (x > 0) {
    x -= 1;
    queen.sing(disagree);
}

String[] phrases = {"Oh", "mamma mia", "let me go"};
System.out.print(phrases[0]);
for (int i = 0; i < 3; i += 1) {
    System.out.print(" "+phrases[1]);
}
System.out.print(" "+phrases[2]);
```

2 Mystery

Below is a function (or method) called mystery1. It takes an array of integers called inputArray and an integer k as arguments and returns an integer.

```java
public static int mystery1(int[] inputArray, int k) {
    int x = inputArray[k];
    int answer = k;
    int index = k + 1;
    while (index < inputArray.length) {
        if (inputArray[index] < x) {
            x = inputArray[index];
            answer = index;
        }
        index = index + 1;
    }
    return answer;
}
```

Write the return value of mystery1 if inputArray is the array {3, 0, 4, 6, 3} and k is 2. Then, describe in English what mystery1 returns.
Extra: Below is another function called `mystery2`. It takes an array of integers called `inputArray` as an argument and returns nothing.

```java
    public static void mystery2(int[] inputArray) {
        int index = 0;
        while (index < inputArray.length) {
            int targetIndex = mystery1(inputArray, index);
            int temp = inputArray[targetIndex];
            inputArray[targetIndex] = inputArray[index];
            inputArray[index] = temp;
            index = index + 1;
        }
    }
```

Write what `mystery2` will do if `inputArray` is the array `{3, 0, 4, 6, 3}`. Then, describe in English what `mystery2` does.

3 Fibonacci

Implement `fib1` recursively. `fib1` takes in an integer `N` and returns an integer representing the `N`th Fibonacci number. The Fibonacci sequence is 0, 1, 1, 2, 3, 5, 8, 13, 21, …, where 0 is the 0th Fibonacci number.

```java
    public static int fib1(int N) {
    }
```

Extra: Implement `fib2` in 5 lines or fewer that avoids redundant computation. `fib2` takes in an integer `N` and helper arguments `k`, `f0`, and `f1` and returns an integer representing the `N`th Fibonacci number. If you’re stuck, try implementing `fib1` iteratively and then see how you can transform your iterative approach to implement `fib2`.

```java
    public static int fib2(int N, int k, int f0, int f1) {
        }
    ```
