Instructions (Read Me!)

- Don't Panic!
- This booklet contains 6 numbered pages including the cover page. Put all answers on these pages; don't hand in any stray pieces of paper.
- Please turn off all pagers, cell phones & beepers. Remove all hats & headphones. Place your backpacks, laptops and jackets at the front. Sit in every other seat. Nothing may be placed in the "no fly zone" spare seat/desk between students.
- You have 120 minutes to complete this exam. The exam is open book, no computers, PDAs, calculators.
- There may be partial credit for incomplete answers; write as much of the solution as you can. We will deduct points if your solution is far more complicated than necessary. When we provide a blank, please fit your answer within the space provided. You have 2 hours...relax.

Question	1	2	3	4	Total
Minutes	48	24	24	24	120
Points	30	15	15	15	75

1) What is that funky smell? Oh, it's just Potpourri... (continued)

h) Complete the below C code so that it obeys its comments. This should work on 1986 hardware, where `ints` were only 2 bytes wide, as well on our current 32-bit MIPS machines.

```
#define INT_BITS _____; // # bits in an int
// Rotates (the numeral that p points to) to the left by 0<=n<INT_BITS.
// "rotate" means the leftmost bits fall off the left, appear on the right

void drotL(unsigned int *p, unsigned int n) {
    _____ ;
}
```

- i) You define a short recursive MIPS procedure `foo` that is statically linked by two executables. Can the binary for the procedure `foo` be different in the two executables? Why, or why not?
- j) We want to represent 10-digit phone numbers using bits. Assume that any combination of 10 digits is legal. One scheme is to represent *each digit with a certain number of bits*, then repeat it 10 times. What is the minimum number of bits required to represent a phone number using this scheme?
- k) Using any scheme, what is the fewest number of bits required to "address" all phone numbers?

l) Consider the C code here, and assume the `malloc` call succeeds. Rank the following values from 1 to 5, with 1 being the least, right before `bar` returns. Use the memory layout from class; *Treat all addresses as unsigned #s.*

`foo` _____
`&foo` _____
`FIVE` _____
`&FIVE` _____
`&x` _____

```
#include <stdlib.h>
int FIVE = 5;

int bar(int x) {
    return x * x;
}

int main(int argc, char *argv[]) {
    int *foo = malloc(sizeof(int));
    if (foo) free(foo);
    bar(10); // ← snapshot just before it returns
    return 0;
}
```

2) “free at last, thank gosh we are free at last...” (24 min, 15 pts)

We wish to *free* a linked list of strings (example below) whose nodes are made up of this struct. Complete the code below; we have started you off with some filled in. You may use fewer lines, but *do not add any*.

```
// Assume compiler packs tightly
struct node {
    char *string;
    struct node *next;
};
```

```
FreeLL:      beq _____, _____, NULL_CASE
```

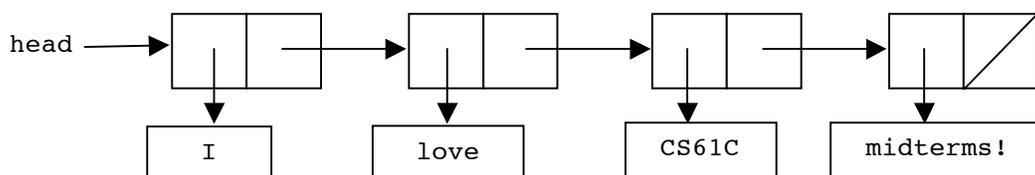

```
jal FreeLL
```

```
lw $a0 0($sp)
```

```
jal free
```

```
NULL_CASE:  jr $ra
```

```
void FreeLL(struct node *ptr) {
    if (ptr == NULL)
        return;
    else {
        FreeLL(ptr->next);
        free(ptr->string);
        free(ptr);
    }
}
```

3) “Cache, money. Dollar bills, y’all.” (24 min, 15 pts)

Suppose we have a standard 32-bit byte-addressed MIPS machine, a single direct-mapped 32KiB cache, a write-through policy, and a 16B block size.

- a) Give the T:I:O breakup. _____
b) How many bits are there per row on the cache? _____

Use the C code below and the description of the cache above to answer the questions that follow it. Suppose that the only memory accesses are accesses and stores to arrays and that all memory accesses in the code are valid. Assume A starts on a block boundary (byte 0 of A in byte 0 of block).

```
#define NUM_INTS 32
#define OFFSET 8192 // 8192 = 2^13

int rand(int x, int y); // returns a random integer in the range [x, y)

int main(){
    int A[NUM_INTS + OFFSET]; // Assume A starts on a block boundary

    // START LOOP 1
    for ( int count = 0 ; count < NUM_INTS ; count += 1 ) { // count by 1s
        A[count] = count; // ACCESS #1
        A[count + OFFSET] = count+count; // ACCESS #2
    }
    // END LOOP 1

    // START LOOP 2
    for ( int count = 0 ; count < NUM_INTS ; count += 4 ) { // count by 4s now
        for ( int r = 0 ; r < 4 ; r++ ) { // ...but do it 4 times
            printf("%d", A[rand(count, count+4)]);
        }
    }
    // END LOOP 2
}
```

- c) Hit rate for Loop 1? _____ What types of misses are there? _____
d) Hit rate for Loop 2? _____ What types of misses are there? _____

Questions (e), (f), and (g) below are three independent variations on the original code & settings.

- e) If the cache were 2-way set associative, what would be the hit rate for Loop 2? _____
(assume the standard LRU replacement policy)
f) If instead we removed the line labeled ACCESS #2, what would be the hit rate for Loop 2? _____
g) Instead, what's the smallest we could shrink OFFSET to maximize our Loop 2 hit rate? _____
(assume we still need to maintain the same functionality)

4) You thought YOUR numbers were big? Try these! (24 min, 15 pts)

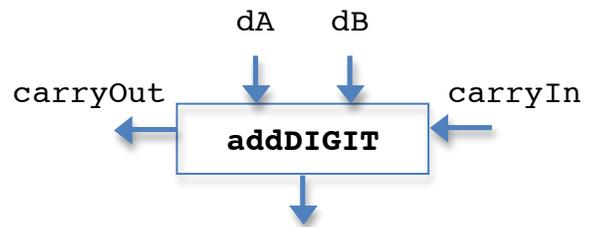

We'd like to represent infinitely long positive integers. We decide to use an array of DIGITS, where a DIGIT is an unsigned 8-bit quantity specified by `uint8_t`. We'd also like to know where the number ends, so we'll declare `0xF` to be the *terminator* (like `0x0` is for strings). Let's see how we'd store "57":

Byte	2								1								0							
Bit	0	0	0	0	1	1	1	1	0	0	0	0	0	1	0	1	0	0	0	0	0	1	1	1
Hex	0				F				0				5				0				7			

- a) Fill in `addDIGIT` to make it work properly. The idea is that we'll build this small black box that can add *one* DIGIT as shown below, then to add the whole thing we'll virtually hook many of these together. This block simulates what we do when we are adding, say, the tens column on the right: **dA** is 2, **dB** is 7, **carryIn** from the ones column is 1, **carryOut** for the hundreds column gets 1 and the return value is 0.

	1	1	
	1	2	8
+	7	7	
	0	5	

```
typedef uint8_t DIGIT;
DIGIT addDIGIT(DIGIT dA, DIGIT dB, DIGIT carryIn, DIGIT *carryOut) {
    uint8_t tempSum = _____
    _____
    return _____
}
```

- b) Now, let's use `addDIGIT` to write the full adder! Unfortunately, there are bugs; indicate your changes to fix the code in the table below. We use two helpers, `sizeofDIGIT()`, which would return 2 for the "57" example above, and `safeDigit()` which takes an array A, index and length returning `A[index]` if we're still in array bounds (`index < length`), and 0 otherwise. A, B are never NULL.

```
01 DIGIT *add-DIGITs(DIGIT *A, DIGIT *B) {
02     unsigned int lenA = sizeofDIGIT(A);
03     unsigned int lenB = sizeofDIGIT(B);
04
05     DIGIT sum[max(lenA, lenB)]; /* make space for the answer */
06     DIGIT carryIn = 0, carryOut;
07     int i;
08     for(i=0 ; i < max(lenA, lenB) ; i++) {
09         sum[i] = addDIGIT(safeDigit(A, i, lenA), safeDigit(B, i, lenB), carryIn, carryOut);
10         carryIn = carryOut;
11     }
12
13     sum[i] = 0xF; /* terminator */
14     return sum;
15 }
```

Line	Indicate the fix here and what it is (insertion, deletion, change). All lines not nec needed.
