a) If a maximum output swing of $0.4 \sim 2.4 \mathrm{~V}$ is desired, design $W / L_{5-8}$.
b) Determine the CM level at nodes $X$ and $Y$ using the $W / L_{5,6}=60 / 0.5$ and $W / L_{7,8}=50 / 0.5$. Use these sizings for all the problems below.
c) If each output is loaded by a $1-\mathrm{pF}$ capacitor, compensate the op amp by Miller capacitors $C_{c}$ across the gates and drains of $M_{5,6}$ for a phase margin of $60^{\circ}$ in unity-gain feedback. Calculate the pole and zero positions after compensation.
d) Design the resistance that must be placed in series with the compensation capacitors to position the zero atop the non-dominant pole.
e) Determine the slew rate.
