Interpretation

Scheme program: foo.scm

Scheme interpreter

- Scheme Interpreter is just a program that reads a scheme program and performs the functions of that scheme program.
Translation

- Scheme Compiler is a translator from Scheme to machine language.
- The processor is a hardware interpreter of machine language.

Diagram:

1. Scheme program: `foo.scm`
2. Scheme Compiler
3. Executable (mach lang pgm): `a.out`
4. Hardware
Steps to Starting a Program (translation)

1. **C program:** foo.c
2. **Compiler**
3. **Assembly program:** foo.s
4. **Assembler**
5. **Object (mach lang module):** foo.o
6. **Linker**
7. **Executable (mach lang pgm):** a.out
8. **Loader**
9. **Memory**
Compiler

- Input: High-Level Language Code (e.g., C, Java such as `foo.c`)
- Output: Assembly Language Code (e.g., `foo.s` for MIPS)
- Note: Output *may* contain pseudoinstructions
- Pseudoinstructions: instructions that assembler understands but not in machine
  
  For example:
  
  - `move $s1,$s2` \(\rightarrow\) or `\$s1,$s2,$zero`
Where Are We Now?

C program: foo.c
Compiler
Assembly program: foo.s
Assembler
Object (mach lang module): foo.o
Linker
Executable (mach lang pgm): a.out
Loader
Memory

CS164
lib.o
Assembler

- Input: Assembly Language Code (MAL) (e.g., foo.s for MIPS)
- Output: Object Code, information tables (TAL) (e.g., foo.o for MIPS)
- Reads and Uses Directives
- Replace Pseudoinstructions
- Produce Machine Language
- Creates Object File
Assembler Directives (p. A-51 to A-53)

- Give directions to assembler, but do not produce machine instructions
  
  `.text:` Subsequent items put in user text segment (machine code)
  
  `.data:` Subsequent items put in user data segment (binary rep of data in source file)
  
  `.globl sym:` declares `sym` global and can be referenced from other files
  
  `.asciiz str:` Store the string `str` in memory and null-terminate it
  
  `.word w1...wn:` Store the `n` 32-bit quantities in successive memory words
Pseudoinstruction Replacement

- Asm. treats convenient variations of machine language instructions as if real instructions

<table>
<thead>
<tr>
<th>Pseudo</th>
<th>Real</th>

<td>ori $a0,$at,right(str)</td>
</tr>
</tbody>
</table>
Produce Machine Language (1/3)

- **Simple Case**
  - Arithmetic, Logical, Shifts, and so on.
  - All necessary info is within the instruction already.

- **What about Branches?**
  - PC-Relative
  - So once pseudo-instructions are replaced by real ones, we know by how many instructions to branch.

- So these can be handled.
Producing Machine Language (2/3)

- “Forward Reference” problem
  - Branch instructions can refer to labels that are “forward” in the program:
    
    ```
    or $v0, $0, $0
    L1: slt $t0, $0, $a1
    beq $t0, $0, L2
    addi $a1, $a1, -1
    j L1
    L2: add $t1, $a0, $a1
    ```
  
  - Solved by taking 2 passes over the program.
    - First pass remembers position of labels
    - Second pass uses label positions to generate code
What about jumps (j and jal)?
- Jumps require **absolute address**.
- So, forward or not, still can’t generate machine instruction without knowing the position of instructions in memory.

What about references to data?
- **la** gets broken up into **lui** and **ori**
- These will require the full 32-bit address of the data.
- These can’t be determined yet, so we create two tables...
Symbol Table

- List of "items" in this file that may be used by other files.
- What are they?
  - Labels: function calling
  - Data: anything in the `.data` section; variables which may be accessed across files
Relocation Table

- List of “items” this file needs the address later.
- What are they?
  - Any label jumped to: `j` or `jal`
    - internal
    - external (including lib files)
  - Any piece of data
    - such as the `la` instruction
Object File Format

- **object file header**: size and position of the other pieces of the object file
- **text segment**: the machine code
- **data segment**: binary representation of the data in the source file
- **relocation information**: identifies lines of code that need to be “handled”
- **symbol table**: list of this file’s labels and data that can be referenced
- **debugging information**

A standard format is ELF (except MS)

http://www.skyfree.org/linux/references/ELF_Format.pdf
Where Are We Now?

C program: foo.c

Assembly program: foo.s

Assembler

Object (mach lang module): foo.o

Linker

Executable (mach lang pgm): a.out

Loader

Memory

lib.o
**Linker (1/3)**

- **Input:** Object Code files, information tables (e.g., `foo.o`, `libc.o` for MIPS)
- **Output:** Executable Code (e.g., `a.out` for MIPS)
- Combines several object (.o) files into a single executable ("linking")
- Enable Separate Compilation of files
  - Changes to one file do not require recompilation of whole program
    - Windows NT source was > 40 M lines of code!
  - Old name “Link Editor” from editing the “links” in jump and link instructions
Linker (2/3)

```
.o file 1
  text 1
  data 1
  info 1

.o file 2
  text 2
  data 2
  info 2

Linker
```

```
  a.out
  Relocated text 1
  Relocated text 2
  Relocated data 1
  Relocated data 2
```
Linker (3/3)

- Step 1: Take text segment from each `.o` file and put them together.
- Step 2: Take data segment from each `.o` file, put them together, and concatenate this onto end of text segments.
- Step 3: Resolve References
  - Go through Relocation Table; handle each entry
  - That is, fill in all absolute addresses
Four Types of Addresses we’ll discuss

- PC-Relative Addressing (beq, bne)
  - never relocate

- Absolute Address (j, jal)
  - always relocate

- External Reference (usually jal)
  - always relocate

- Data Reference (often lui and ori)
  - always relocate
Absolute Addresses in MIPS

- Which instructions need relocation editing?
  - J-format: jump, jump and link
    
    | j/jal | xxxxx |
    |-------|-------|
  - Loads and stores to variables in static area, relative to global pointer
    
    | lw/sw | $gp  | $x   | address |
    |-------|------|------|---------|
  - What about conditional branches?
    
    | beq/bne | $rs | $rt | address |
    |---------|-----|-----|---------|
  - PC-relative addressing preserved even if code moves
Resolving References (1/2)

- Linker assumes first word of first text segment is at address \texttt{0x00000000}.
  - (More later when we study “virtual memory”)

- Linker knows:
  - length of each text and data segment
  - ordering of text and data segments

- Linker calculates:
  - absolute address of each label to be jumped to (internal or external) and each piece of data being referenced
Resolving References (2/2)

- To resolve references:
  - search for reference (data or label) in all "user" symbol tables
  - if not found, search library files (for example, for `printf`)
  - once absolute address is determined, fill in the machine code appropriately

- Output of linker: executable file containing text and data (plus header)
Where Are We Now?

- C program: foo.c
- Compiler
- Assembly program: foo.s
- Assembler
- Object (mach lang module): foo.o
- Linker
- Executable (mach lang pgm): a.out
- Loader
- Memory

CS164

lib.o
Loader Basics

- Input: Executable Code (e.g., `a.out` for MIPS)
- Output: (program is run)
- Executable files are stored on disk.
- When one is run, loader’s job is to load it into memory and start it running.
- In reality, loader is the operating system (OS)
  - loading is one of the OS tasks
Loader ... what does it do?

- Reads executable file’s header to determine size of text and data segments
- Creates new address space for program large enough to hold text and data segments, along with a stack segment
- Copies instructions and data from executable file into the new address space
- Copies arguments passed to the program onto the stack
- Initializes machine registers
  - Most registers cleared, but stack pointer assigned address of 1st free stack location
- Jumps to start-up routine that copies program’s arguments from stack to registers & sets the PC
  - If main routine returns, start-up routine terminates program with the exit system call
Conclusion

- Compiler converts a single HLL file into a single assembly language file.
- Assembler removes pseudo instructions, converts what it can to machine language, and creates a checklist for the linker (relocation table). A .s file becomes a .o file.
  - Does 2 passes to resolve addresses, handling internal forward references
- Linker combines several .o files and resolves absolute addresses.
  - Enables separate compilation, libraries that need not be compiled, and resolves remaining addresses
- Loader loads executable into memory and begins execution.

- Stored Program concept is very powerful. It means that instructions sometimes act just like data. Therefore we can use programs to manipulate other programs!
  - Compiler ⇒ Assembler ⇒ Linker ⇒ Loader
Peer Instruction

Which of the following instr. may need to be edited during link phase?

Loop: lui $at, 0xABCD
     ori $a0,$at, 0xFEDC # 1
     bne $a0,$v0, Loop  # 2
Which of the following instr. may need to be edited during link phase?

Loop:  
\[
\begin{align*}
&\text{lui } \$at, 0xABCD \\
&\text{ori } \$a0,\$at, 0xFEDC \\
&\text{bne } \$a0,\$v0, \text{Loop} \\
\end{align*}
\]

- a) FF  
- b) FT  
- c) TF  
- d) TT  

**Peer Instruction Answer**

- c) TF

**Reasoning:**
- **lui $at, 0xABCD** (Load Immediate): This instruction does not affect the program counter and does not need to be edited during the link phase.
- **ori $a0,$at, 0xFEDC** (Or Immediate): This instruction also does not affect the program counter and does not need to be edited during the link phase.
- **bne $a0,$v0, Loop** (Branch on Not Equal): This instruction is a program counter (PC)-relative branch and may need to be edited during the link phase if the relocation information is not correctly managed.

Therefore, the instruction that may need to be edited during the link phase is the PC-relative branch instruction. The correct answer is **c) TF**.
1) Assembler will ignore the instruction **Loop: nop** because it does nothing.

2) Java designers used a translator AND interpreter (rather than just a translator) mainly because of (at least 1 of): ease of writing, better error msgs, smaller object code.
1) Assembler keeps track of all labels in symbol table...F!

2) Java designers used both mainly because of code portability...F!

1) Assembler will ignore the instruction **Loop: nop** because it does nothing.

2) Java designers used a translator AND interpreter (rather than just a translator) **mainly** because of (at least 1 of): ease of writing, better error msgs, smaller object code.
Bonuses slides

- These are extra slides that used to be included in lecture notes, but have been moved to this, the “bonus” area to serve as a supplement.
- The slides will appear in the order they would have in the normal presentation.
Language Execution Continuum

- An Interpreter is a program that executes other programs.

Language translation gives us another option.

In general, we interpret a high level language when efficiency is not critical and translate to a lower level language to up performance.
Interpretation vs Translation

- How do we run a program written in a source language?
  - **Interpreter**: Directly executes a program in the source language
  - **Translator**: Converts a program from the source language to an equivalent program in another language

- For example, consider a Scheme program `foo.scm`
Interpretation

- Any good reason to interpret machine language in software?
- SPIM – useful for learning / debugging
- Apple Macintosh conversion
  - Switched from Motorola 680x0 instruction architecture to PowerPC.
    - Similar issue with switch to x86.
  - Could require all programs to be re-translated from high level language
  - Instead, let executables contain old and/or new machine code, interpret old code in software if necessary (emulation)
Interpretation vs. Translation? (1/2)

- Generally easier to write interpreter
- Interpreter closer to high-level, so can give better error messages (e.g., MARS, stk)
  - Translator reaction: add extra information to help debugging (line numbers, names)
- Interpreter slower (10x?), code smaller (2x?)
- Interpreter provides instruction set independence: run on any machine
Interpretation vs. Translation? (2/2)

- Translated/compiled code almost always more efficient and therefore higher performance:
  - Important for many applications, particularly operating systems.

- Translation/compilation helps “hide” the program “source” from the users:
  - One model for creating value in the marketplace (eg. Microsoft keeps all their source code secret)
  - Alternative model, “open source”, creates value by publishing the source code and fostering a community of developers.
Static vs Dynamically linked libraries

- What we’ve described is the traditional way: **statically-linked** approach
  - The library is now part of the executable, so if the library updates, we don’t get the fix (have to recompile if we have source)
  - It includes the entire library even if not all of it will be used.
  - Executable is self-contained.

- An alternative is **dynamically linked libraries (DLL)**, common on Windows & UNIX platforms
Dynamically linked libraries

- Space/time issues
  - + Storing a program requires less disk space
  - + Sending a program requires less time
  - + Executing two programs requires less memory (if they share a library)
  - – At runtime, there’s time overhead to do link

- Upgrades
  - + Replacing one file (libXYZ.so) upgrades every program that uses library “XYZ”
  - – Having the executable isn’t enough anymore

Overall, dynamic linking adds quite a bit of complexity to the compiler, linker, and operating system. However, it provides many benefits that often outweigh these.
Dynamically linked libraries

- The prevailing approach to dynamic linking uses machine code as the “lowest common denominator”
  - The linker does not use information about how the program or library was compiled (i.e., what compiler or language)
  - This can be described as “linking at the machine code level”
  - This isn’t the only way to do it...
Example: C $\rightarrow$ Asm $\rightarrow$ Obj $\rightarrow$ Exe $\rightarrow$ Run

C Program Source Code: prog.c

```c
#include <stdio.h>

int main (int argc, char *argv[]) {
    int i, sum = 0;
    for (i = 0; i <= 100; i++)
        sum = sum + i * i;
    printf ("The sum of sq from 0 .. 100 is %d\n", sum);
}
```

"printf" lives in "libc"
Compilation: MAL

```assembly
.text
.align 2
.globl main
main:
    subu $sp,$sp,32
    sw $ra, 20($sp)
    sd $a0, 32($sp)
    sw $0, 24($sp)
    sw $0, 28($sp)
loop:
    lw $t6, 28($sp)
    mul $t7, $t6,$t6
    lw $t8, 24($sp)
    addu $t9,$t8,$t7
    sw $t9, 24($sp)
    addu $t0, $t6, 1
    sw $t0, 28($sp)
    ble $t0,100, loop
    la $a0, str
    lw $a1, 24($sp)
    jal printf
    move $v0, $0
    lw $ra, 20($sp)
    addiu $sp,$sp,32
    jr $ra
.data
.align 0
str:
.asciiz "The sum of sq from 0 .. 100 is %d\n"
```

Where are 7 pseudo-instructions?
Compilation: MAL

```asm
.text
.align 2
.globl main
main:
    subu $sp,$sp,32
    sw $ra, 20($sp)
    sd $a0, 32($sp)
    sw $0, 24($sp)
    sw $0, 28($sp)
loop:
    lw $t6, 28($sp)
    mul $t7, $t6,$t6
    lw $t8, 24($sp)
    addu $t9,$t8,$t7
    sw $t9, 24($sp)
    addu $t0, $t6, 1
    sw $t0, 28($sp)
    ble $t0,100, loop
    la $a0, str
    lw $a1, 24($sp)
    jal printf
    move $v0, $0
    lw $ra, 20($sp)
    addiu $sp,$sp,32
    jr $ra

.data
.align 0
str:
.asciiz "The sum of sq from 0 .. 100 is %d\n"
```

7 pseudo-instructions underlined
Assembly step 1:

Remove pseudoinstructions, assign addresses

<p>| | | |</p>

</table>
Link step 1: combine prog.o, libc.o

- Merge text/data segments
- Create absolute memory addresses
- Modify & merge symbol and relocation tables

Symbol Table

- Label          Address
  main:           0x00000000
  loop:           0x00000018
  str:            0x10000430
  printf:         0x000003b0 ...

Relocation Information

- Address        Instr. Type  Dependency
  0x00000040      lui            l.str
  0x00000044      ori            r.str
  0x0000004c      jal            printf ...

### Link step 2:

- Edit Addresses in relocation table
  - (shown in TAL for clarity, but done in binary)

<table>
<thead>
<tr>
<th>Line</th>
<th>Instruction</th>
<th>Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>addiu $29,$29,-32</td>
<td></td>
</tr>
<tr>
<td>04</td>
<td>sw $31,20($29)</td>
<td></td>
</tr>
<tr>
<td>08</td>
<td>sw $4, 32($29)</td>
<td></td>
</tr>
<tr>
<td>0c</td>
<td>sw $5, 36($29)</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>sw $0, 24($29)</td>
<td></td>
</tr>
<tr>
<td>14</td>
<td>sw $0, 28($29)</td>
<td></td>
</tr>
<tr>
<td>18</td>
<td>lw $14, 28($29)</td>
<td></td>
</tr>
<tr>
<td>1c</td>
<td>multu $14, $14</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>mflo $15</td>
<td></td>
</tr>
<tr>
<td>24</td>
<td>lw $24, 24($29)</td>
<td></td>
</tr>
<tr>
<td>28</td>
<td>addu $25,$24,$15</td>
<td></td>
</tr>
<tr>
<td>2c</td>
<td>sw $25, 24($29)</td>
<td></td>
</tr>
<tr>
<td>30</td>
<td>addiu $8,$14, 1</td>
<td></td>
</tr>
<tr>
<td>34</td>
<td>sw $8,28($29)</td>
<td></td>
</tr>
<tr>
<td>38</td>
<td>slti $1,$8, 101</td>
<td></td>
</tr>
<tr>
<td>3c</td>
<td>bne $1,$0, -10</td>
<td></td>
</tr>
<tr>
<td>40</td>
<td>lui $4, 4096</td>
<td></td>
</tr>
<tr>
<td>44</td>
<td>ori $4,$4, 1072</td>
<td></td>
</tr>
<tr>
<td>48</td>
<td>lw $5,24($29)</td>
<td></td>
</tr>
<tr>
<td>4c</td>
<td>jal 812</td>
<td></td>
</tr>
<tr>
<td>50</td>
<td>add $2, $0, $0</td>
<td></td>
</tr>
<tr>
<td>54</td>
<td>lw $31,20($29)</td>
<td></td>
</tr>
<tr>
<td>58</td>
<td>addiu $29,$29,32</td>
<td></td>
</tr>
<tr>
<td>5c</td>
<td>jr $31</td>
<td></td>
</tr>
</tbody>
</table>
Link step 3:

- Output executable of merged modules.
  - Single text (instruction) segment
  - Single data segment
  - Header detailing size of each segment

- NOTE:
  - The preceeding example was a much simplified version of how ELF and other standard formats work, meant only to demonstrate the basic principles.
## Integer Multiplication (1/3)

- Paper and pencil example (unsigned):
  
  \[
  \begin{array}{c}
  \text{Multiplicand} \quad 1000 \quad 8 \\
  \text{Multiplier} \quad \underline{x1001} \quad 9 \\
  \hline
  1000 \\
  0000 \\
  0000 \\
  +1000 \\
  \hline
  01001000
  \end{array}
  \]

- \( m \) bits \( \times \) \( n \) bits = \( m + n \) bit product
Integer Multiplication (2/3)

- In MIPS, we multiply registers, so:
  - 32-bit value x 32-bit value = 64-bit value

- Syntax of Multiplication (signed):
  - `mult register1, register2`
  - Multiplies 32-bit values in those registers & puts 64-bit product in special result regs:
    - puts product upper half in hi, lower half in lo
  - hi and lo are 2 registers separate from the 32 general purpose registers
  - Use `mfhi register` & `mflo register` to move from hi, lo to another register
Integer Multiplication (3/3)

- **Example:**
  - in C: \( a = b \times c; \)
  - in MIPS:
    - let \( b \) be \( $s2 \); let \( c \) be \( $s3 \); and let \( a \) be \( $s0 \) and \( $s1 \) (since it may be up to 64 bits)
      
      ```
      mult $s2,$s3   # b*c
      mfhi $s0       # upper half of
      # product into $s0
      mflo $s1       # lower half of
      # product into $s1
      ```

- **Note:** Often, we only care about the lower half of the product.
Integer Division (1/2)

- Paper and pencil example (unsigned):

\[
\begin{array}{c|cccc}
\text{Divisor} & 1000 & 1001010 & \text{Quotient} & 1001 \\
-1000 & 10 & 101 & \text{Dividend} \\
101 & 1010 \\
1010 & -1000 & 10 & \text{Remainder} \\
-1000 & \text{(or Modulo result)}
\end{array}
\]

- Dividend = Quotient \times \text{Divisor} + \text{Remainder}
### Integer Division (2/2)

- **Syntax of Division (signed):**
  - `div register1, register2`
  - Divides 32-bit register 1 by 32-bit register 2:
  - Puts remainder of division in `hi`, quotient in `lo`

- **Implements C division (`/`) and modulo (`%`)**

- **Example in C:**
  
  ```
  a = c / d;    b = c % d;
  ```

- **In MIPS:**
  
  ```
  a←$s0; b←$s1; c←$s2; d←$s3
  div $s2,$s3    # lo=c/d, hi=c%d
  mflo $s0       # get quotient
  mfhi $s1       # get remainder
  ```
**Big Endian vs. Little Endian**

Big-endian and little-endian derive from Jonathan Swift's *Gulliver's Travels* in which the Big Endians were a political faction that broke their eggs at the large end ("the primitive way") and rebelled against the Lilliputian King who required his subjects (the Little Endians) to break their eggs at the small end.

- The order in which *BYTES* are stored in memory
- Bits always stored as usual. *(E.g., 0xC2=0b 1100 0010)*

Consider the number 1025 as we normally write it:

<table>
<thead>
<tr>
<th>BYTE3</th>
<th>BYTE2</th>
<th>BYTE1</th>
<th>BYTE0</th>
</tr>
</thead>
<tbody>
<tr>
<td>10101010</td>
<td>11011010</td>
<td>10001100</td>
<td>10101010</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ADDR3</th>
<th>ADDR2</th>
<th>ADDR1</th>
<th>ADDR0</th>
<th>ADDR3</th>
<th>ADDR2</th>
<th>ADDR1</th>
<th>ADDR0</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE0</td>
<td>BYTE1</td>
<td>BYTE2</td>
<td>BYTE3</td>
<td>BYTE0</td>
<td>BYTE1</td>
<td>BYTE2</td>
<td>BYTE3</td>
</tr>
<tr>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
</tr>
</tbody>
</table>

Big Endian

<table>
<thead>
<tr>
<th>ADDR0</th>
<th>ADDR1</th>
<th>ADDR2</th>
<th>ADDR3</th>
<th>ADDR0</th>
<th>ADDR1</th>
<th>ADDR2</th>
<th>ADDR3</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE3</td>
<td>BYTE2</td>
<td>BYTE1</td>
<td>BYTE0</td>
<td>BYTE3</td>
<td>BYTE2</td>
<td>BYTE1</td>
<td>BYTE0</td>
</tr>
<tr>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
<td>00000000</td>
</tr>
</tbody>
</table>

Little Endian
