

Announcements

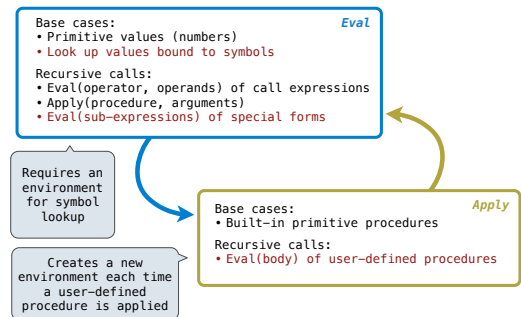

- Project 1 composition revisions due Thursday 11/7 @ 11:59pm.
- Homework 8 due Tuesday 11/12 @ 11:59pm, and it's in Scheme!
- Project 4 due Thursday 11/21 @ 11:59pm, and it's a Scheme interpreter!
- **New Policy:** An improved final exam score can make up for low midterm scores.
 - If you scored less than 60/100 midterm points total, then you can earn some points back.
 - You don't need a perfect score on the final to do so.

61A Lecture 26

Wednesday, November 6

Interpreting Scheme

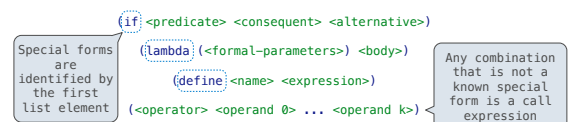

The Structure of an Interpreter

Scheme Evaluation

- The `scheme_eval` function dispatches on expression form:
- Symbols are bound to values in the current environment.
 - Self-evaluating expressions are returned.
 - All other legal expressions are represented as Scheme lists, called *combinations*.

Special Forms

```
(define (demo s) (if (null? s) '(3) (cons (car s) (demo (cdr s)))))  
  
(demo (list 1 2))
```

Logical Forms

Logical Special Forms

Logical forms may only evaluate some sub-expressions.

- **If expression:** `(if <predicate> <consequent> <alternative>)`
- **And and or:** `(and <e1> ... <en>)`, `(or <e1> ... <en>)`
- **Cond expr'n:** `(cond (<p1> <e1>) ... (<pn> <en>) (else <e>))`

The value of an `if` expression is the value of a sub-expression.

- Evaluate the predicate.
- Choose a sub-expression: `<consequent>` or `<alternative>`.
- Evaluate that sub-expression in place of the whole expression.

do_if_form

scheme_eval

(Demo)

Quotation

Quotation

The `quote` special form evaluates to the quoted expression, which is **not** evaluated.

```
(quote <expression>)      (quote (+ 1 2))  evaluates to the  
                           three-element Scheme list  (+ 1 2)
```

The `<expression>` itself is the value of the whole quote expression.

'<expression> is shorthand for `(quote <expression>)`.

```
(quote (1 2))  is equivalent to  '(1 2)
```

The `scheme_read` parser converts shorthand to a combination.

(Demo)

Lambda Expressions

Lambda Expressions

Lambda expressions evaluate to user-defined procedures.

```
(lambda (<formal-parameters>) <body>)  
  
(lambda (x) (* x x))
```

class LambdaProcedure:

```
def __init__(self, formals, body, env):  
    self.formals = formals          A scheme list of symbols  
    self.body = body               A scheme expression  
    self.env = env                 A Frame instance
```

Frames and Environments

A frame represents an environment by having a parent frame.

Frames are Python instances with methods `lookup` and `define`.

In Project 4, Frames do not hold return values.

(Demo)

Define Expressions

Define Expressions

Define binds a symbol to a value in the first frame of the current environment.

```
(define <name> <expression>)
```

1. Evaluate the `<expression>`.

2. Bind `<name>` to its value in the current frame.

```
(define x (+ 1 2))
```

Procedure definition is shorthand of define with a lambda expression.

```
(define (<name> <formal parameters>) <body>)
```

```
(define <name> (lambda (<formal parameters>) <body>))
```

Applying User-Defined Procedures

To apply a user-defined procedure, create a new frame in which formal parameters are bound to argument values, whose parent is the `env` of the procedure.

Evaluate the body of the procedure in the environment that starts with this new frame.

```
(define (demo s) (if (null? s) '(3) (cons (car s) (demo (cdr s)))))
(demo (list 1 2))
```

Eval/Apply in Lisp 1.5

```

apply[fn;x;a] =
  [atom[fn] → [eq[fn;CAR] → caar[x];
    eq[fn;CDR] → cdar[x];
    eq[fn;CONS] → cons[car[x];cadr[x]];
    eq[fn;ATOM] → atom[car[x]];
    eq[fn;EQ] → eq[car[x];cadr[x]];
    T → apply[eval[fn;a];x;a]];
  eq[car[fn];LAMBDA] → eval[caddr[fn];pairlis[cadr[fn];x;a]];
  eq[car[fn];LABEL] → apply[caddr[fn];x;cons[cons[cadr[fn];
    cadr[fn]];a]]];

eval[e;a] = [atom[e] → cdr[assoc[e;a]];
  atom[car[e]] →
  [eq[car[e];QUOTE] → cadr[e];
    eq[car[e];COND] → evcon[cdr[e];a];
    T → apply[car[e];evlis[cdr[e];a];a]];
  T → apply[car[e];evlis[cdr[e];a];a]]
  
```

Dynamic Scope

Dynamic Scope

The way in which names are looked up in Scheme and Python is called *lexical scope* (or *static scope*).

Lexical scope: The parent of a frame is the environment in which a procedure was *defined*.

Dynamic scope: The parent of a frame is the environment in which a procedure was *called*.

```
(define f (lambdamu (x) (+ x y)))  
(define g (lambda (x y) (f (+ x x))))  
(g 3 7)
```

Special form to create dynamically scoped procedures

Lexical scope: The parent for f's frame is the global frame.

Error: unknown identifier: y

Dynamic scope: The parent for f's frame is g's frame.
