Today:

- Priority queues \textit{(Data Structures §6.4, §6.5)}
- Range queries (§6.2)
- Java utilities: \texttt{SortedSet}, \texttt{Map}, etc.
Priority Queues, Heaps

- Priority queue: defined by operations “add,” “find largest,” “remove largest.”

- Examples: scheduling long streams of actions to occur at various future times.

- Also useful for sorting (keep removing largest).

- Common implementation is the heap, a kind of tree.

- (Confusingly, this same term is used to described the pool of storage that the new operator uses. Sorry about that.)
Heaps

- A max-heap is a binary tree that enforces the
  *Heap Property*: Labels of *both* children of each node are less than node’s label.

- So the node at top has largest label.

- Looser than binary search property, which allows us to keep tree “bushy”.

- That is, it’s always valid to put the smallest nodes anywhere at the bottom of the tree.

- Thus, heaps can be made *nearly complete*: all but possibly the last row have as many keys as possible.

- As a result, insertion of new value and deletion of largest value always take time proportional to $\lg N$ in worst case.

- A min-heap is basically the same, but with the minimum value at the root and children having larger values than their parents.
Example: Inserting into a simple heap

Data:
1 17 4 5 9 0 -1 20

Initial Heap:

Add 8: Dashed boxes show where the heap property is violated

re-heapify up
Heap insertion continued

Now insert 18:
Removing Largest from Heap

To remove largest: Move the bottommost, rightmost node to the top, then re-heapify down as needed (swap offending node with larger child) to re-establish the heap property.

Initial

Final
Heaps in Arrays

- Since heaps are nearly complete (missing items only at bottom level), can use arrays for compact representation.
- Example of removal from last slide (dashed arrows show children):

Nodes stored in level order.
Children of node at index $#K$ are in $2K$ and $2K + 1$ if numbering from 1, or $2K + 1$ and $2K + 2$ if from 0.
Ranges

- So far, we have looked for specific items,
- But for BSTs, we need an ordering anyway, and we can also support looking for ranges of values.
- Example: perform some action on all values in a BST that are within some range (in natural order):

```java
/** Apply WHATTODO to all labels in T that are >= L and < U, in ascending natural order. */
static void visitRange(BST<String> T, String L, String U, Consumer<BST<String>> whatToDo) {
    if (T != null) {
        int compLeft = L.compareTo(T.label ()),
                      compRight = U.compareTo(T.label ());
        if (compLeft < 0) /* L < label */
            visitRange (T.left(), L, U, whatToDo);
        if (compLeft <= 0 && compRight > 0) /* L <= label < U */
            whatToDo.accept(T);
        if (compRight > 0) /* label < U */
            visitRange (T.right (), L, U, whatToDo);
    }
}
```
Time for Range Queries

- Time for range query $\in O(h + M)$, where $h$ is the height of the tree, and $M$ is the number of data items that turn out to be in the range.
- Consider searching the tree below for all values $25 \leq x < 40$.
- Dashed nodes are never looked at. Starred nodes are looked at but not output. The $h$ comes from the starred nodes; the $M$ comes from unstarred non-dashed nodes.
Ordered Sets and Range Queries in Java

- **Class** `SortedSet` supports range queries with *views* of a set:
  - `S.headSet(U)`: subset of `S` that is `< U`
  - `S.tailSet(L)`: subset that is `≥ L`
  - `S.subSet(L,U)`: subset that is `≥ L, < U`

- Changes to views modify `S`.

- Attempts to, e.g., add to a `headSet` beyond `U` are disallowed.

- Can iterate through a view to process a range:

  ```java
  SortedSet<String> fauna = new TreeSet<String>
      (Arrays.asList("axolotl", "elk", "dog", "hartebeest", "duck"));
  for (String item : fauna.subSet("bison", "gnu"))
      System.out.printf("%s, ", item);
  
  would print “dog, duck, elk,”
  ```
TreeSet

• Java library type TreeSet<T> requires either that T be Comparable, or that you provide a Comparator, as in:

    SortedSet<String> rev_fauna = new TreeSet<String>(Collections.reverseOrder());

• Comparator is a type of function object:

    interface Comparator<T> {
        /** Return <0 if LEFT<RIGHT, >0 if LEFT>RIGHT, else 0. */
        int compare(T left, T right);
    }

    (We’ll deal with what Comparator<T extends Comparable<T>> is all about later.)

• For example, the reverseOrder comparator is defined like this:

    /** A Comparator that gives the reverse of natural order. */
    static <T extends Comparable<T>> Comparator<T> reverseOrder() {
        // Java figures out this lambda expression is a Comparator<T>.
        return (x, y) -> y.compareTo(x);
    }
Example of Representation: BSTSet

- Same representation for both sets and subsets.
- Pointer to BST, plus bounds (if any).
- `.size()` is expensive!

```java
SortedSet<String> fauna = new BSTSet<String>(stuff);
subset1 = fauna.subSet("bison","gnu");
subset2 = subset1.subSet("axolotl","dog");
```
# Comparing Search Structures

Here, $N$ is the number of items, $k$ is the number of answers to a query.
