Lecture 10 – Introduction to MIPS Procedures I

2014-09-22

APPLE DRAWS VERY PUBLIC LINE ON PRIVACY

Apple took a bold step recently to showcase its commitment to privacy: how they've built privacy in, how to manage privacy, and government information requests. How "if a service is free, you're the product" isn't true for them. Transparency is critical here, bravo.

Review

- MIPS Machine Language Instruction: 32 bits representing a single instruction

R	opcode	rs	rt	rd	shamt	funct
I	opcode	rs	rt	immediate		
J	opcode	target address				

- Branches use PC-relative addressing, Jumps use absolute addressing.
- Disassembly is simple and starts by decoding opcode field. (more next lecture)

C functions

```
main() {
   int i,j,k,m;
   ...
   i = mult(j,k); ...
   m = mult(i,i); ...
}

/* really dumb mult function */

int mult (int mcand, int mlier){
   int product = 0;
   while (mlier > 0)  {
     product = product + mcand;
     mlier = mlier -1; }
   return product;
   }
```

What information must compiler/programmer keep track of?

What instructions can accomplish this?

Function Call Bookkeeping

- Registers play a major role in keeping track of information for function calls.
- Register conventions:
  - Return address `$ra`
  - Arguments `$a0, $a1, $a2, $a3`
  - Return value `$v0, $v1`
  - Local variables `$s0, $s1, … , $s7`
- The stack is also used; more later.

Instruction Support for Functions (1/6)

C

```
... sum(a,b);... /* a,b:$s0,$s1 */
 }
 int sum(int x, int y) {
    return x+y;
 }
```

MIPS

```
address (shown in decimal)
 1000
 1004
 1008
 1012
 1016
 …
 2000
 2004
```

In MIPS, all instructions are 4 bytes, and stored in memory just like data. So here we show the addresses of where the programs are stored.

Instruction Support for Functions (2/6)

C

```
... sum(a,b);... /* a,b:$s0,$s1 */
 }
 int sum(int x, int y) {
    return x+y;
 }
```

MIPS

```
address (shown in decimal)
 1000 add  $a0,$s0,$zero  # x = a
 1004 add  $a1,$s1,$zero  # y = b
 1008 addi $ra,$zero,1016 #$ra=1016
 1012 j    sum            #jump to sum
 1016
 …
 2000 sum: add $v0,$a0,$a1
 2004 jr   $ra            # new instruction
```

Instruction Support for Functions (3/6)

C

```
... sum(a,b);... /* a,b:$s0,$s1 */
}
int sum(int x, int y) {
   return x+y;
}
```

MIPS

- Question: Why use `jr` here? Why not use `j`?
- Answer: `sum` might be called by many places, so we can't return to a fixed place. The calling proc to `sum` must be able to say "return here" somehow.

```
2000 sum: add $v0,$a0,$a1
2004 jr   $ra          # new instruction
```

Instruction Support for Functions (4/6)

- Single instruction to jump and save return address: jump and link (`jal`)
- Before:

```
1008 addi $ra,$zero,1016 #$ra=1016
1012 j sum               #goto sum
```

- After:

```
1008 jal sum  # $ra=1012,goto sum
```

- Why have a `jal`?
  - Make the common case fast: function calls very common.
  - Don't have to know where code is in memory with `jal`!

Instruction Support for Functions (5/6)

- Syntax for **`jal`** (jump and link) is same as for **j** (jump):

  `jal  label`

- **`jal`** should really be called **`laj`** for "link and jump":
  - Step 1 (link): Save address of *next* instruction into `$ra`
    - Why next instruction? Why not current one?
  - Step 2 (jump): Jump to the given label

Instruction Support for Functions (6/6)

- Syntax for **`jr`** (jump register):

  `jr register`

- Instead of providing a label to jump to, the **`jr`** instruction provides a register which contains an address to jump to.
- Very useful for function calls:
  - **`jal`** stores return address in register (`$ra`)
  - **`jr $ra`** jumps back to that address

Nested Procedures (1/2)

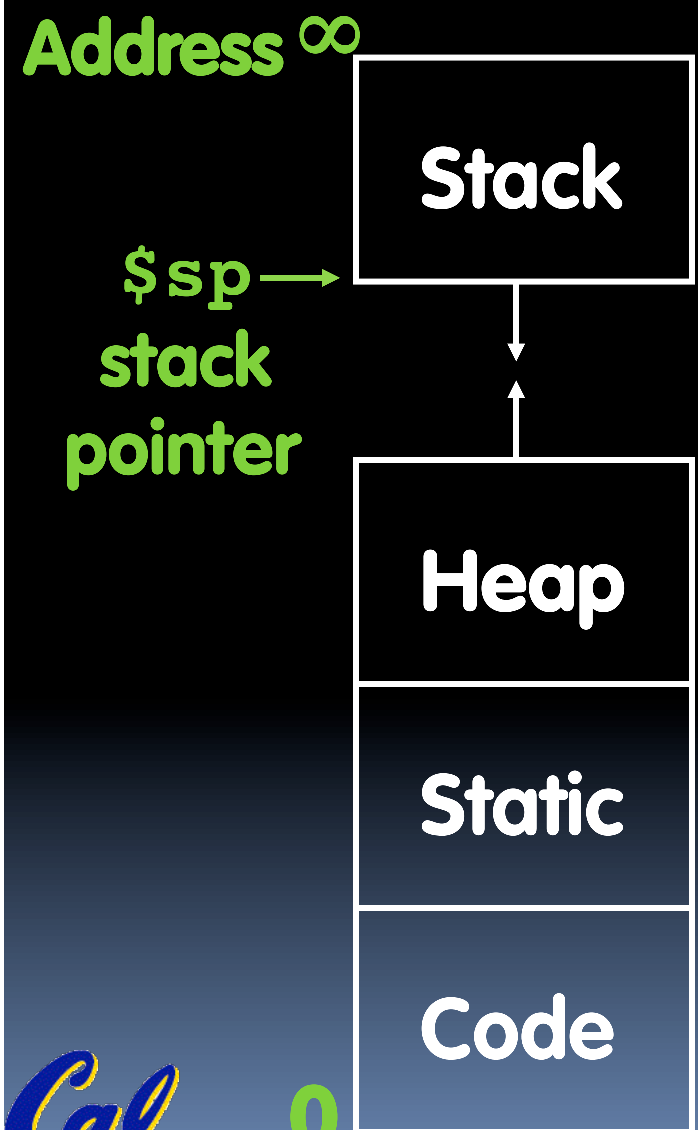
```
int sumSquare(int x, int y) {
   return mult(x,x)+ y;
}
```

- Something called **`sumSquare`**, now **`sumSquare`** is calling **`mult`**.
- So there's a value in `$ra` that **`sumSquare`** wants to jump back to, but this will be overwritten by the call to **`mult`**.
- Need to save **`sumSquare`** return address before call to **`mult`**.

Nested Procedures (2/2)

- In general, may need to save some other info in addition to `$ra`.
- When a C program is run, there are 3 important memory areas allocated:
  - Static: Variables declared once per program, cease to exist only after execution completes. E.g., C globals
  - Heap: Variables declared dynamically via **malloc**
  - Stack: Space to be used by procedure during execution; this is where we can save register values

C Memory Allocation



Space for local vars, saved procedure information

Explicitly created space, i.e., `malloc()`

Variables declared once per program; e.g., globals (doesn't change size)

Program (doesn't change size)

Using the Stack (1/2)

- So we have a register `$sp` which always points to the last used space in the stack.
- To use stack, we decrement this pointer by the amount of space we need and then fill it with info.
- So, how do we compile this?

```
int sumSquare(int x, int y) {
    return mult(x,x)+ y;
}
```

Using the Stack (2/2)

- Hand-compile

```
int sumSquare(int x, int y) {
    return mult(x,x)+ y; }
```

```
sumSquare:
        addi $sp,$sp,-8  # space on stack
        sw $ra, 4($sp)   # save ret addr
"push"  sw $a1, 0($sp)   # save y
        add $a1,$a0,$zero # mult(x,x)
        jal mult          # call mult
        lw $a1, 0($sp)   # restore y
        add $v0,$v0,$a1  # mult()+y
"pop"   lw $ra, 4($sp)   # get ret addr
        addi $sp,$sp,8   # restore stack
        jr $ra
mult: ...
```

Steps for Making a Procedure Call

1. Save necessary values onto stack.
2. Assign argument(s), if any.
3. `jal` call
4. Restore values from stack.

Rules for Procedures

- Called with a `jal` instruction, returns with a `jr $ra`
- Accepts up to 4 arguments in `$a0`, `$a1`, `$a2` and `$a3`
- Return value is always in `$v0` (and if necessary in `$v1`)
- Must follow register conventions

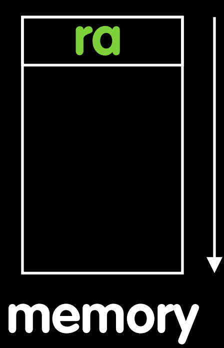
  So what are they?

Basic Structure of a Function

Prologue

```
entry_label:
addi $sp,$sp, -framesize
sw $ra, framesize-4($sp)  # save $ra
save other regs if need be
```

Body . . .   (call other functions…)



Epilogue

```
restore other regs if need be
lw $ra, framesize-4($sp)  # restore $ra
addi $sp,$sp, framesize
jr $ra
```

MIPS Registers

The constant 0	`$0`	`$zero`
Reserved for Assembler	`$1`	`$at`
Return Values	`$2-$3`	`$v0-$v1`
Arguments	`$4-$7`	`$a0-$a3`
Temporary	`$8-$15`	`$t0-$t7`
Saved	`$16-$23`	`$s0-$s7`
More Temporary	`$24-$25`	`$t8-$t9`
Used by Kernel	`$26-27`	`$k0-$k1`
Global Pointer	`$28`	`$gp`
Stack Pointer	`$29`	`$sp`
Frame Pointer	`$30`	`$fp`
Return Address	`$31`	`$ra`

(From COD green insert)
Use names for registers -- code is clearer!

Other Registers

- `$at`: may be used by the assembler at any time; unsafe to use
- `$k0-$k1`: may be used by the OS at any time; unsafe to use
- `$gp`, `$fp`: don't worry about them
- Note: Feel free to read up on `$gp` and `$fp` in Appendix A, but you can write perfectly good MIPS code without them.

Peer Instruction

```
int fact(int n){
 if(n == 0) return 1; else return(n*fact(n-1));}
```

When translating this to MIPS…

1) We COULD copy `$a0` to `$a1` (& then not store `$a0` or `$a1` on the stack) to store n across recursive calls.
2) We MUST save `$a0` on the stack since it gets changed.
3) We MUST save `$ra` on the stack since we need to know where to return to…

e)	TTF
e)	TTT

"And in Conclusion…"

- Functions called with `jal`, return with `jr $ra`.
- The stack is your friend: Use it to save anything you need. Just leave it the way you found it!
- Instructions we know so far…

  Arithmetic: `add, addi, sub, addu, addiu, subu`

  Memory: `lw, sw, lb, sb`

  Decision: `beq, bne, slt, slti, sltu, sltiu`

  Unconditional Branches (Jumps): `j, jal, jr`
- Registers we know so far
  - All of them!
